Functional Programming in Typed Racket

Florian Florian

IT University of Copenhagen & UCAS

2016-05-26

Just call me Florian!

▶ I am from Germany and live in Denmark.

- ▶ I am from Germany and live in Denmark.
- Second year PhD student at IT University of Copenhagen and UCAS.

- ▶ I am from Germany and live in Denmark.
- Second year PhD student at IT University of Copenhagen and UCAS.
- My Chinese is really bad (but I am trying to learn!)

- My Chinese is really bad (but I am trying to learn!)
- If you do not understand what I say or if I speak too fast, please tell me right away!

GitHub Course Page

All slides and course materials are available on:

https://github.com/fbie/parallel-functional-lectures

Functional programming is old but recently it has become very popular!

▶ Makes it easier to think about what a program does.

- Makes it easier to think about what a program does.
- ► Parallel in its nature → easy to parallelize (next lecture).

- ▶ Makes it easier to think about what a program does.
- Parallel in its nature → easy to parallelize (next lecture).
- Used in financial industry, modern compilers and more.

- Makes it easier to think about what a program does.
- ► Parallel in its nature → easy to parallelize (next lecture).
- Used in financial industry, modern compilers and more.
- Jobs in functional programming pay better!

Racket and its sister-language **Typed Racket** are Scheme-dialects.

Racket and its sister-language **Typed Racket** are Scheme-dialects.

Racket is dynamically typed, Typed Racket has a static, strong type system.

Racket and its sister-language **Typed Racket** are Scheme-dialects.

- Racket is dynamically typed, Typed Racket has a static, strong type system.
- Functional language, no side-effects (mostly).

Racket and its sister-language **Typed Racket** are Scheme-dialects.

- Racket is dynamically typed, Typed Racket has a static, strong type system.
- ► Functional language, no side-effects (mostly).
- Good for meta-programming (we won't look at that).

Hello World in Typed Racket

```
;; Tell run-time which language to use.
#lang typed/racket

;; Now print something.
(print "Nihao!")
```

A More Interesting Program

```
#lang typed/racket
;; Define x as the result of the computation.
(define x (* (+ 2 4) (+ 42 9)))
```

A More Interesting Program

```
#lang typed/racket
;; Define x as the result of the computation.
(define x (* (+ 2 4) (+ 42 9)))
We can check its value in the interactive mode:
> x
59
```

Do You Think This Looks Strange?

In Racket, all expressions are written like this:

```
(function arg1 arg2 ... argN)
```

Do You Think This Looks Strange?

In Racket, all expressions are written like this:

```
(function arg1 arg2 ... argN)
```

Operators are also just functions:

$$\begin{array}{cccc} (+ & x & y) & \Rightarrow & x + y \\ (> & x & y) & \Rightarrow & x > y \\ (/ & x & y) & \Rightarrow & \frac{x}{y} \\ (f & x & y) & \Rightarrow & f(x, y) \end{array}$$

Do You Think This Looks Strange?

In Racket, all expressions are written like this:

Operators are also just functions:

$$\begin{array}{cccc} (+ & x & y) & \Rightarrow & x + y \\ (> & x & y) & \Rightarrow & x > y \\ (/ & x & y) & \Rightarrow & \frac{x}{y} \\ (f & x & y) & \Rightarrow & f(x, y) \end{array}$$

Some functions are variadic:

$$(+ x y z) \Rightarrow x + y + z$$

Local Bindings

Just like local variables in Java, but you can never change them!

What does this program do?

Note: You cannot reference x and y after the last closing parenthesis of the let expression!

The Same Program in Java

```
int x = 2 * 16;
int y = 3 * 17;
x + y;
```

```
#lang typed/racket
(: times-two (-> Number Number))
(define (times-two x)
  (* 2 x))
```

```
#lang typed/racket
(: times-two (-> Number Number))
(define (times-two x)
  (* 2 x))
```

Several new things on this slide:

```
#lang typed/racket
(: times-two (-> Number Number))
(define (times-two x)
  (* 2 x))
```

Several new things on this slide:

► Functions need no return statement. Their return value is the last executed statement!

```
#lang typed/racket
(: times-two (-> Number Number))
(define (times-two x)
  (* 2 x))
```

Several new things on this slide:

- ► Functions need no return statement. Their return value is the last executed statement!
- Type annotations start with : and describe the type of a symbol.

```
#lang typed/racket
(: times-two (-> Number Number))
(define (times-two x)
  (* 2 x))
```

Several new things on this slide:

- ► Functions need no return statement. Their return value is the last executed statement!
- Type annotations start with : and describe the type of a symbol.
- ► The type of times-two is Number → Number.

Types in Typed Racket

We write the function type $A \rightarrow B$ as:

$$(-> A B)$$

where A is the parameter type and B is the return type.

Types in Typed Racket

We write the function type $A \rightarrow B$ as:

$$(-> A B)$$

where A is the parameter type and B is the return type.

Which types are parameter types, which ones are return types?

Polymorphic Types

Polymorphic types in Typed Racket are very explicit:

```
(: twice (All (A) (-> A (Pairof A A))))
(define (twice a)
  (pair a a))
```

Polymorphic Types

Polymorphic types in Typed Racket are very explicit:

```
(: twice (All (A) (-> A (Pairof A A))))
(define (twice a)
  (pair a a))
```

"For all types A, the type of twice is such that iff you pass it a value of some type A it will return a pair of values of type A."

Polymorphic Types

Polymorphic types in Typed Racket are very explicit:

```
(: twice (All (A) (-> A (Pairof A A))))
(define (twice a)
  (pair a a))
```

"For all types A, the type of twice is such that iff you pass it a value of some type A it will return a pair of values of type A."

It's just like generic types in Java!

The Same Program in Java

```
public class Pairof <A> {
  public final A fst, snd;
  public Pairof(A a) {
    fst = a;
    snd = a;
  public static Pairof <A> twice(A a) {
    return new Pairof <A>(a);
```

Note: There is no build-in pair type in Java :(

Local Bindings, Revisited

Let's turn our local binding example into a function!

Local Bindings, Revisited

Let's turn our local binding example into a function!

Now, we can call it like any other function:

```
> (two-three-sum 1 1)
5
> (two-three-sum 20 20)
100
```

Anonymous Functions

You can define functions without giving them a name. Such functions are called *lambda expressions*:

```
> ((lambda (x) x) 2)
2
```

Anonymous Functions

You can define functions without giving them a name. Such functions are called *lambda expressions*:

```
> ((lambda (x) x) 2)
2
```

Here, we have defined a lambda expression and applied it to the value 2. We call this function the *identity function*.

Anonymous Functions

You can define functions without giving them a name. Such functions are called *lambda expressions*:

```
> ((lambda (x) x) 2)
2
```

Here, we have defined a lambda expression and applied it to the value 2. We call this function the *identity function*.

We will often come across lambda expressions in functional programming!

Structs in Typed Racket

Structs are containers for values.

```
(struct (myNumberBox [value : Number]))
(struct (myStringBox [value : String]))
```

Structs in Typed Racket

Structs are containers for values.

```
(struct (myNumberBox [value : Number]))
(struct (myStringBox [value : String]))
```

We can also use type polymorphism here:

```
(struct (A) (myPolyBox [value : A]))
```

Next, we will do a live coding session!

► I code on the big screen and show you how to do functional programming in Racket.

- ► I code on the big screen and show you how to do functional programming in Racket.
- You help with ideas and suggestions and experiment yourselves!

- ► I code on the big screen and show you how to do functional programming in Racket.
- You help with ideas and suggestions and experiment yourselves!
- All code we write will be available on

Java Equivalent to Maybe

```
public abstract class Maybe < A > {}
public class None < A > extends Maybe < A > {
  public None() {}
}
public class Some < A > extends Maybe < A > {
  public final A a;
  public Some(A a) {
    this.a = a;
```

Java Equivalent to Cons List

```
public abstract class LinkedList <A> {}
public class Nil<A> extends LinkedList<A> {
  public Nil() {}
}
public class Cons<A> extends LinkedList<A> {
  public final A a;
  public final LinkedList <A> tail;
  public Cons(A a, LinkedList <A> tail) {
    this.a = a;
    this.tail = tail;
```

Java Equivalent to Binary Tree

```
public abstract class BinaryTree<A> {}
public class Leaf <A> extends BinaryTree <A> {
  public final A a;
  public Leaf(A a) {
    this.a = a;
public class Node<A> extends BinaryTree<A> {
  public final BinaryTree <A> left, right;
  public Node(BinaryTree < A > left,
              BinaryTree < A > right) {
    this.left = left; this.right = right;
```
